Project Overiew

- We are constructing a lock-free version of a Pairing heap (a self-balancing heap.)
- Pairing heaps have an efficient decreaseKey implementation (near-constant performance) that allow you to decrease the value in a heap without reinserting it.
- This improves the asymptotic performance of certain algorithms (e.g., Dijkstra's algorithm.)
- We are comparing our heap against Skipqueues (a priority queue backed with a Skiplist.)

Dijkstra's Algorithm

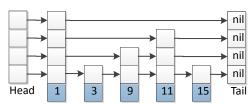

Single-Source Shortest Path Problem

In a weighted graph G=(V,E), find the shortest path from a target vertex $v\in V$ to all other vertices in the graph.

- Push every node in a graph into a priority queue (PQ.) In the PQ, each node is weighted by current information we have about their distance.
- Initially, all nodes have a distance of ∞ , except the target node, which has a distance of 0.
- Dynamic programming approach: Inductively build up our shortest routes.
 - Pop off the node on the PQ with the smallest distance. (The shortest path from the source to this node is finished.)
 - Update the weights in the PQ with the distances emanating from the popped node.

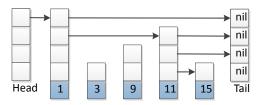

Skiplists

- Skiplists are constructed from a hierarchy of linked lists with the Skiplist property: the set of elements contained in level i is a subset of all the levels below it.
- Links allow you to do a binary search and "jump" around a list.
- The height of an element is randomly sampled from a power-law distribution: the probability of a node having a height of $i \geq 0$ is 2^{-i} .
- Time complexity of operations are probabilistically the same as for a binary search tree, but $\mathcal{O}(n)$ in the worst case.

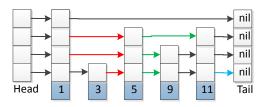

Skiplists (Search)

- For each level, move right until you run into a node greater than your target. Then, from this point, move right on the next lowest level, and repeat.
- Likely runs in $\mathcal{O}(\log n)$ time.
- Head / tail nodes have values of $-\infty$ and ∞ , respectively.

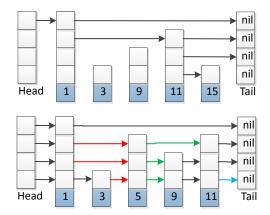

Next and Previous Windows

- A useful abstraction to make is the set of all pointers related to a given node. (Aggregate all the pointers related to one node.)
- ullet prev[i]
 ightarrow the node in level i pointing to the target node.
- $next[i] \rightarrow$ the node the target node points to at level i.
- Use the search process to construct these sets.

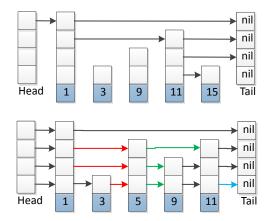

Skiplists (Insertion)

 Insertion: Find the location the target should be at. Set all of the node's next pointers to next[i] and set the next pointers at each prev[i] to the new node.

Skiplists (Deletion)

 Deletion: Set all of the next pointers in prev[i] equal to next[i].

Lock-free Skiplists

- Instead of linked lists at each level, we use lock-free linked lists.
- We lose the Skiplist property. (Levels aren't necessarily subsets of each other.) In particular, this means we need to always verify a node is in the lowest level.

Lock-free Skiplists

- Instead of linked lists at each level, we use lock-free linked lists.
- Linearization point: membership is defined at the lowest level of the Skiplist.
- We lose the Skiplist property. (Levels aren't necessarily subsets of each other.) In particular, this means we need to always verify a node is in the lowest level.

Lock-Free Skiplists (Insertion)

- ullet Construct the prev[i] and next[i] sets.
- ullet Set all of the node's next pointers to next[i].
- If we can CAS the node into the bottom level, continue.
 Otherwise, something changed, and restart (reconstruct prev[i] and next[i]).
- Next, CAS all prev[i] to the new node. If a CAS fails, reconstruct prev[i].

Lock-Free Skiplists (Deletion)

- Pointers are atomically markable.
 - In C / C++, steal a bit from the pointer.
 - In Java, use AtomicMarkableReference.
- Construct the prev[i] and next[i] sets.
- For each pointer in our target node, mark them as deleted.

Optimized decreaseKey for Lock-Free Skiplists

- Currently, to implement a decreaseKey for Skiplists, we need to do two $\mathcal{O}(\log n)$ operations (one insert and one delete.)
- We can optimize this in some cases by removing redundant work: reuse the prev[i] set as a starting point for the next insertion.

Pairing Heaps

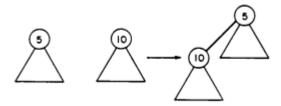

- Pairing Heaps were introduced by Fredman and Tarjan¹ as a simplification of Fibonacci heaps.
 - \bullet Fibonacci heaps have a $\mathcal{O}(1)$ decreaseKey operator, but require complicated rebalancing.
- decreaseKey runs in $2^{\mathcal{O}(\sqrt{\log\log n})}$ time.
 - In practice, constant time. E.g., for a graph with a billion edges, $2^{\sqrt{\log\log 10^9}} = 3.34$.
- Pairing heaps have better performance than Fibonacci heaps on reasonably-sized graphs.²

¹ "The Pairing heap: a new form of self-adjusting heap," Fredman, Sedgewick, Sleator, and Tarjan, Algorithmica (1986).

Pairing Heaps: Melding Two Heaps

- To meld two heaps, compare their roots and add the root as a child of the smaller root.
- meld is the core operator for Pairing heaps.

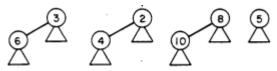

Pairing Heaps: deleteMin

• Pairing heaps have a two-step deleteMin operator.

Pairing Heaps: deleteMin

• After removing the root, meld each pair of heaps.

Pairing Heaps: deleteMin

• meld each resultant heap from right-to-left.
